

**Step 1: Install R**

Step 1b: Mac users also need to install XQuartz. (<https://www.xquartz.org/releases/XQuartz-2.7.7.html>)

**Step 2: Open R****Step 3: Run this code:**

```
install.packages("lavaan") #Even if you already installed lavaan, you will need to update it.  
install.packages("shiny")  
library(shiny)  
runGitHub("connet", "leander-ds")
```

**Step 4:** Wait until application opens. R will first install all packages necessary for the app to launch. Next time you run the app R will not need to install all the packages, so it will start up faster.

**Step 5:** To open the app again in the future, you can just run these two lines:

```
library(shiny)  
runGitHub("connet", "leander-ds")
```

About

## Select the estimator

ML

Run CFA with these settings

## Is the data clustered?

☒ No ☐ Yes

## Orthogonal

☒ FALSE ☐ TRUE

## Mimic

☒ lavaan ☐ Mplus ☐ EQS

## Which models do you want to include?

- ☒ Proposed Measurement Model
- ☒ All models where two constructs are merged into one
- ☒ Harman's single factor test
- ☐ Proposed model with unmeasured latent methods factor
- ☐ Proposed model with unmeasured latent methods factor with fixed factor loadings

The CFA Specification tab allows you to specify the settings of the models you want to run.

Here you can decide which estimator to use, whether to run a clustered CFA, and which models to include in the table.

Once you have made your decisions, you can click on "Run CFA with these settings".

A loading screen will then appear while the app runs all your models and places them in a table.

This is often done within a few seconds

Showing

In this table common indices of the proposed and nested measurement models are reported. All models are also compared to the proposed measurement model (i.e. Chisq.Diff).

For example, “*Passion\_and\_NeedForCalling*” refers to the CFA model in which all items of ‘*Passion*’ and ‘*NeedForCalling*’ are indicators of the same factor. In the table we can see that this did not improve the fit.

You can add more indices using the column selector at the top.

Measurement Model: ProposedModel

###

lavaan 0.6-8 ended normally after 52 iterations

Estimator	ML	
Optimization method	NLMINB	
Number of model parameters	63	
	Used	Total
Number of observations	1073	1696

Model Test User Model:

Test statistic	1093.708
Degrees of freedom	146
P-value (Chi-square)	0.000

Model Test Baseline Model:

Test statistic	11759.579
Degrees of freedom	171
P-value	0.000

User Model versus Baseline Model:

Comparative Fit Index (CFI)	0.918
Tucker-Lewis Index (TLI)	0.904

Loglikelihood and Information Criteria:

Here we can look at the detailed CFA output. This is the output you would get if you ran the CFA in R using the lavaan package (Rosseel, 2012). ConMet also uses the lavaan package.

You can choose which measurement model you want to look at.

In this output you can also look at all the factor loadings and correlations between latent factors.

The output can be downloaded in a .txt-file.

## Reliabilities

	alpha	omega	AVE	SV_Passion	SV_NeedForCalling	SV_CallingInflex	SV_ClarifyID
Passion	0.871	0.874	0.699	1	0.168	0.332	0.171
NeedForCalling	0.788	0.783	0.344	0.168	1	0.051	0.061
CallingInflex	0.787	0.8	0.482	0.332	0.051	1	0.189
ClarityID	0.947	0.949	0.824	0.171	0.061	0.189	1

You can also check the reliabilities (Cronbach's Alpha and McDonald Omega), the Average Variance Extracted (e.g., how much variance of the latent construct does the average item explain) and the Shared Variance between the constructs.

This is helpful if you want to look at other indices of convergent and discriminant validity.
